Android sdk location in mac. Mac os android studio sdk location. Android sdk location in android studio. Android studio sdk location macos. Mac android studio sdk location. How to set android sdk location in android studio.

After you installed android studio, you still need to configure some android SDK environment variables then you can use them easily. This article will tell you how to correctly configure Android SDK environment variables such as ANDROID_HOME, PATH on both Windows and macOS. 1. Configure Android SDK Variable In Windows. 1.1 Get Android SDK Install Directory Path. Before you can configure it, you should first get the android SDK install directory following the steps below. Open android studio, click File -> Settings menu item in the top menu bar. Expand Appearance & Behavior -> System Settings -> Android SDK menu item on the left side of the popup window. Then you can find the Android SDK Location directory path on the right side (in this example, the Android SDK location path is C:\Users\jerry\AppData\Local\Android\Sdk), remember it. 1.2 Set %ANDROID_HOME% and %Path% System Environment Variable. Right-click the computer icon in Windows file explorer left side, click Properties menu item in the popup menu list. This will open the windows system configuration window. Click the Advanced system settings link on the left panel, it will popup the System Properties window, click the Environment Variables button to open the Environment Variables window. Click the New... button to add a new system variable, input ANDROID_HOME as the variable name, and input the Android SDK Location directory path (such as C:\Users\Administrator\AppData\Local\Android\Sdk) as the variable value. Select variable Path and click Edit button and add %ANDROID_HOME%\tools;%ANDROID_HOME%\platform-tools at the end of its value. Please note the ; must be English character otherwise, it will not take effect. Click OK to close the system environment variables settings window, open a dos window, type command adb in it. If you see output like below that means the android SDK path variable has been configured successfully. C:\Users\Administrator>adb Android Debug Bridge version 1.0.39 Version 0.0.1-4500957 Installed as C:\Users\Administrator\AppData\Local\Android\Sdk\platform-tools\adb.exe. 2. Configure Android SDK Variable In macOS. Open Android Studio on macOS, then click Android Studio -> Preferences menu item at the left top toolbar. Input search keyword sdk in the search box of the popup Preferences dialog window left side. It will focus on the Android SDK menu item on the left side, and you can get the Android SDK Location directory path value on the right side Android SDK Location text box. Generally, the Android SDK is installed in the /Users/user-name/Library/Android/sdk folder on macOS. If you can not find the above folder in macOS finder or terminal, this is because the Library folder is a hidden folder by default, you should make the hidden folder visible by executing the command \$ defaults write com.apple.finder AppleShowAllFiles TRUE in a macOS terminal window (please read article How To Show Hidden Files In Mac OS Finder And Select Hidden Files In Html Upload File Form). You can also see the hidden Library folder by opening a macOS Finder window, then click Go -> Go to Folder... menu item, and input ~/Library in the popup dialog input text box, then click Go button. This is also another method to show the hidden Library folder, open a macOS Finder window, click Go -> Home menu item. Right-click the home folder, then click the Show View Options menu item in the popup menu list. Check the Show Library Folder checkbox. Use nano to create or edit user bash profile in user home directory. \$ nano ~/.bash_profile. Add ANDROID_HOME and PATH environment variable in user bash profile. export ANDROID_HOME=/Users/Jerry/Library/Android/sdk export PATH=\$PATH:\$ANDROID_HOME/tools:\$ANDROID_HOME/platform-tools Make the added system environment take effect. \$ source ~/.bash_profile Now open a terminal and run adb, you should also see something output like in windows. 3. How To Download And Install Android SDK Command Line Tool Manually. If you do not need Android Studio, and you just want to use android SDK command-line tools only, it is very easy also. Go to the android SDK command-line tools download page and download the related zip files. Unzip the zip file to a local folder for example C:\android-sdk. Now when you start the Android Studio for the next time, it will let you select the android SDK location folder, just select the above folder. You can also change the android SDK location folder in the Android Studio Settings dialog. For Windows, start Android Studio, then click File -> Settings menu item. For macOS, start Android Studio, then click Android Studio -> Preferences menu item. Select Appearance & Behavior -> System Settings -> Android SDK menu item in the popup window left side. On the window right side, click the Edit link after the Android SDK Location text box, it will open the SDK Setup dialog. At the bottom of the SDK Setup dialog, there is an Android SDK Location text box, you can browse the new Android SDK folder to use it. The sdkmanager is a command-line tool that allows you to view, install, update, and uninstall packages for the Android SDK. If you're using Android Studio, then you do not need to use this tool and you can instead manage your SDK packages from the IDE. The sdkmanager tool is provided in the Android SDK Command-Line Tools package. To use the SDK Manager to install a version of the android line tools, follow these steps: Download the latest "command line tools only" package from the Android Studio downloads page and unzip the package. This is also another method to show the hidden Library folder, open a macOS Finder window, click Go -> Home menu item. Right-click the home folder, then click the Show View Options menu item in the popup menu list. Check the Show Library Folder checkbox. Move the original cmdline-tools directory contents, including the lib directory, bin directory, NOTICE.txt file, and source.properties file, into the newly created latest directory. You can now use the command line tools from this location. (Optional) To install a previous version of the cmdline-tools directory, create a sub-directory called latest. Move the original cmdline-tools directory contents, including the lib directory, bin directory, NOTICE.txt file, and source.properties file, into the newly created latest directory. You can now use the command line tools from this location. (Optional) To install a previous version of the cmdline-tools directory, run the following command: android_sdk\cmdline-tools\latest\bin\sdksdkmanager --install "cmdline-tools;version" Substitute version with the version you want to install, for example 5.0. Note: For local usage, you can use the latest packages, but for scripts, choose a specific version instead to ensure stability. Usage You can use the sdkmanager to perform the following tasks. List installed and available packages sdksdkmanager --list [options] [-channel=channel_id] // Channels: 0 (stable), 1 (beta), 2 (dev), or 3 (canary) Use the channel option to include a package from a channel up to and including channel id. For example, specify the canary channel to list packages from all channels. Note: To list only stable packages, use --channel=0 or remove the --channel option entirely. Install packages sdksdkmanager packages [options] The packages argument is an SDK-style path as shown with the --list command, wrapped in quotes (for example, "build-tools;30.0.2" or "platforms;android-29"). You can pass multiple package paths, separated with a space, but they must each be wrapped in their own set of quotes. For example, here's how to install the latest platform tools (which includes adb and fastboot) and the SDK tools for API level 28: sdksdkmanager "platform-tools" "platforms;android-28" Alternatively, you can pass a text file that specifies all packages: sdksdkmanager --package file [options] The package file argument is the location of a text file in which each line is an SDK-style path of a package to install (without quotes). To uninstall, simply add the --uninstall flag: sdksdkmanager --uninstall packages [options] sdksdkmanager --uninstall --package file [options] To install CMake or the NDK, use the following syntax: sdksdkmanager --install ["ndk;major.minor.build[suffix]"] [-channel=channel_id] // NDK channels: 0 (stable), 1 (beta), or 3 (canary) For example, use the following command to install the specified NDK version regardless of which channel it is currently on. sdksdkmanager --install "ndk;21.3.6528147" --channel=3 // Install the NDK from the canary channel (or below) sdksdkmanager --install "cmake;10.24988404" // Install a specific version of CMake sdksdkmanager --update [options] Options The following table lists the available options for the above commands. Option Description --sdk_root=path Use the specified SDK path instead of the SDK containing this tool --channel=channel_id Include packages in channels up to and including channel id. Available channels are: 0 (Stable), 1 (Beta), 2 (Dev), and 3 (Canary). --include-obsolete Include obsolete packages in the package listing or package updates. For use with --list and --update only. --no-https Force all connections to use HTTP rather than HTTPS. --verbose Verbose output mode. Errors, warnings and informational messages are printed. --proxy={http | socks} Connect via a proxy of the given type: either http for high level protocols such as HTTP or FTP, or socks for a SOCKS (V4 or V5) proxy. --proxy_host={IP address | DNS address} IP or DNS address of the proxy to use. --proxy_port=port_number Proxy port number to connect to. Note: If you want to install packages for an operating system different from the current machine, set the REPO_OS_OVERRIDE environment variable to either "windows", "macosx", or "linux".
